**Table 1.** Characteristics of the cases presenting with same-sex attraction/gender nonconformity and history of maternal thyroid dysfunction in pregnancy.

Case	Sex	Age	Principal psychiatric diagnosis	Records relating to same-sex attraction/gender non-conformity	Reported pregnancy thyroid dysfunction in pregnancy	Medication used for thyroid dysfunction	Additional notes
1	M	15	No diagnosis	Effeminate behavior; plucking eyebrows; subject to homophobic bullying at school	Goiter	No	-
2	M	14	Major depression	Effeminate behavior; in love with a male friend; subject to homophobic bullying at school	Hashimoto thyroiditis	No	-
3	M	10	Anxiety disorder	Shaving body hair; subject to homophobic bullying at school	Hypothyroidism	Yes	-
4	M	11	Learning disorder	Effeminate behavior; subject to homophobic bullying at school	Hashimoto thyroiditis	Yes	-
5	M	11	Asperger disorder	Effeminate behavior; subject to homophobic bullying at school	Hypothyroidism	No	History of postnatal thyroid hormone use for 2 months
6	M	9	ADHD	Parental concerns regarding sexuality; seen peeping other boys' genitals on several occasions	Hashimoto thyroiditis	Yes	-
7	M	17	No diagnosis	Sexual activity with a male friend; admits same-sex orientation	Goiter	No	-
8	M	13	No diagnosis	Sexual play with a male friend; admits same-sex orientation	Hypothyroidism	No	Anti-thyroid medication use before pregnancy
9	M	11	Anxiety disorder	Sexual play with other boys; subject to homophobic bullying at school	Hypothyroidism	No	-
10	M	17	Major depression	Effeminate behavior; in love with a male friend; previously subject to homophobic bullying at school	Hypothyroidism	No	-
11	F	16	Anxiety disorder	An affair with a masculine girl	Hashimoto thyroiditis	No	Also had Hashimoto thyroiditis
12	F	17	ADHD	Sexual activity with a female friend; admits bisexual orientation	Hashimoto thyroiditis	No	Also had Hashimoto thyroiditis

M, Male; F, Female; ADHD, attention deficit/hyperactivity disorder.

## Maternal Hypothyroidism

Andersen (2014b)	Retrospective; N = 542 100, all live-born singletons born between 1980 and 1990 in Denmark	–	Hospital-diagnosed or treated hypothyroidism before 1996 (N = 3979) (information obtained from DNHR and DNPR)	–	Prescription of anxiolytics, antipsychotics, and antidepressants at least twice (information obtained from DNPR)	15–31 years	Maternal hypothyroidism was associated with an increased risk of prescription of anxiolytics and antipsychotics (adjusted hazard ratio (aHR) 1.23 and 1.22 respectively)
Päkkilä (2014)	Longitudinal; N = 5131 mother-child pairs (Northern Finland Birth Cohort 1986)	TSH, fT4, TPO-Ab	TSH > 3.1 mU/l (first trimester) or TSH > 3.5 mU/l	Mean (SD) = 10.7 (2.8) weeks GA	Rutter B2 scale (teacher-rated); combined ADHD symptoms defined as total Rutter B2 scores of ≥9 and 3 or more points from ADHD questions	8 years	In general, there were no significant differences in the odds of ADHD symptoms in children born to mothers with high and normal serum TSH, but girls had a 1.4-fold odds of combined ADHD symptoms with every natural log increase in maternal TSH

# Maternal thyroid function and psychopathology of the child

## Hypothyroxinemia

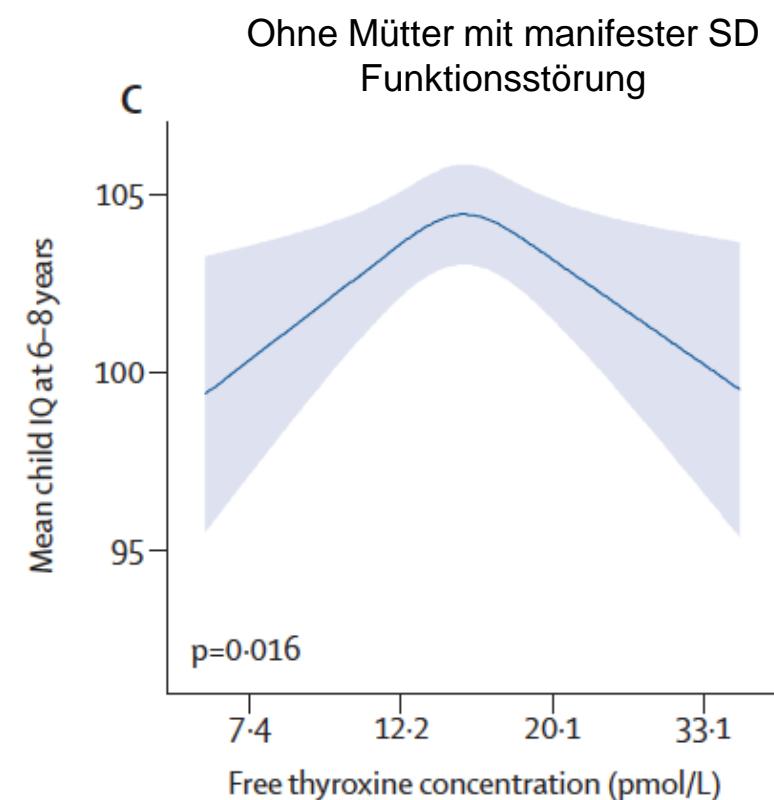

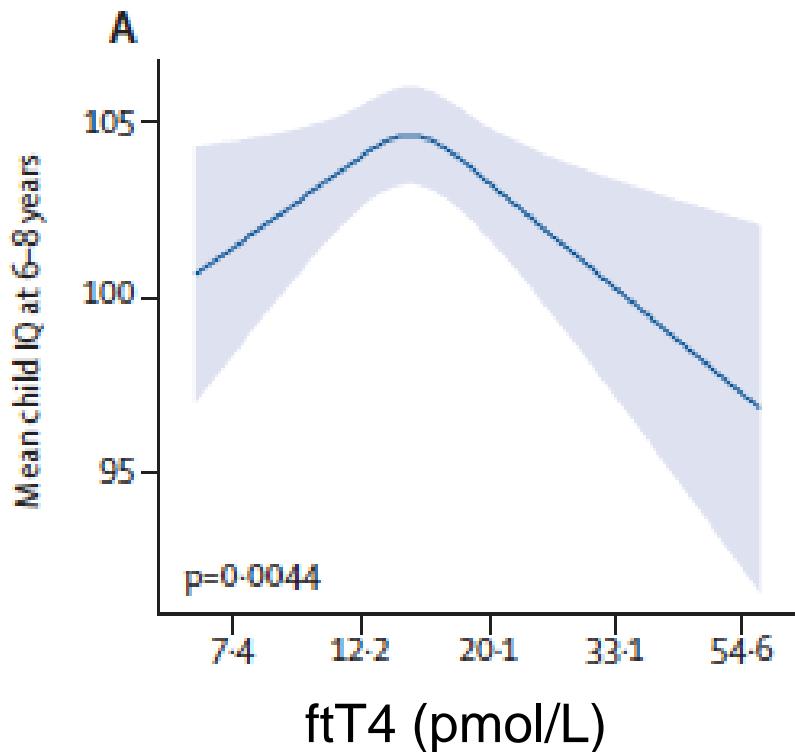

Modesto (2015)	Longitudinal; N = 3873 mother– child pairs (Generation R cohort)	TSH, ft4, TPO-Ab	ft4 < 5th percentile and TSH < 2.5 mU/l (n = 127)	Mean (SD) = 13.6 (1.9) weeks GA	CPRS-R:S	Mean (SD) = 8.1 (0.2) years	Children of hypothyroxinemic women had higher scores on the ADHD index (7% increase) but not on the Oppositional scale compared to nonexposed children
Roman (2013)	Longitudinal; N = 4039 mother– child pairs (Generation R cohort)	TSH, ft4, TPO-Ab	ft4 < 10th percentile and TSH < 2.5 mU/l (n = 295)/ ft4 < 5th percentile and TSH < 2.5 mU/l (n = 136)	Mean (SD) = 13.4 (1.9) weeks GA	PDP subscale of the CBCL 1½– 6 years -5, SRS; probable autism defined by a PDP score > 98th per-centile and SRS score in the top 5% of the sample (n = 81)	6 years	Severe maternal hypothyroxinemia (ft4 < 5th percentile) was associated with an increased risk of having a probable autistic child (adjusted Odds Ratio (aOR) = 3.89) and with higher scores on the PDP and SRS

**TABLE 3.** Possible mechanism for association of cognitive impairment with SH or low serum TSH

---

- A. Excess circulating thyroid hormone resulting in neuronal loss.
  - B. Primary neurodegeneration causes reduced central nervous system TRH secretion, hence lower TSH.
  - C. SH and low TSH are biomarkers for age, and so are associated with other diseases of advanced age including dementias.
  - D. Subjects with cognitive impairment have a high burden of comorbidity, and association is due to nonthyroidal illness and drug effects on serum TSH.

Only a fraction of patients with major depression show biomedical signs of thyroid dysfunction (Bauer et al., 2008; Hage and Azar, 2012).

25–30% of depressed patients show a blunted TSH response to TRH (Loosen, 1985). These findings suggest a chronic TRH hypersecretion by the PVN leading to a downregulation of pituitary TRH receptors, which may be mediated by elevated levels of cortisol.

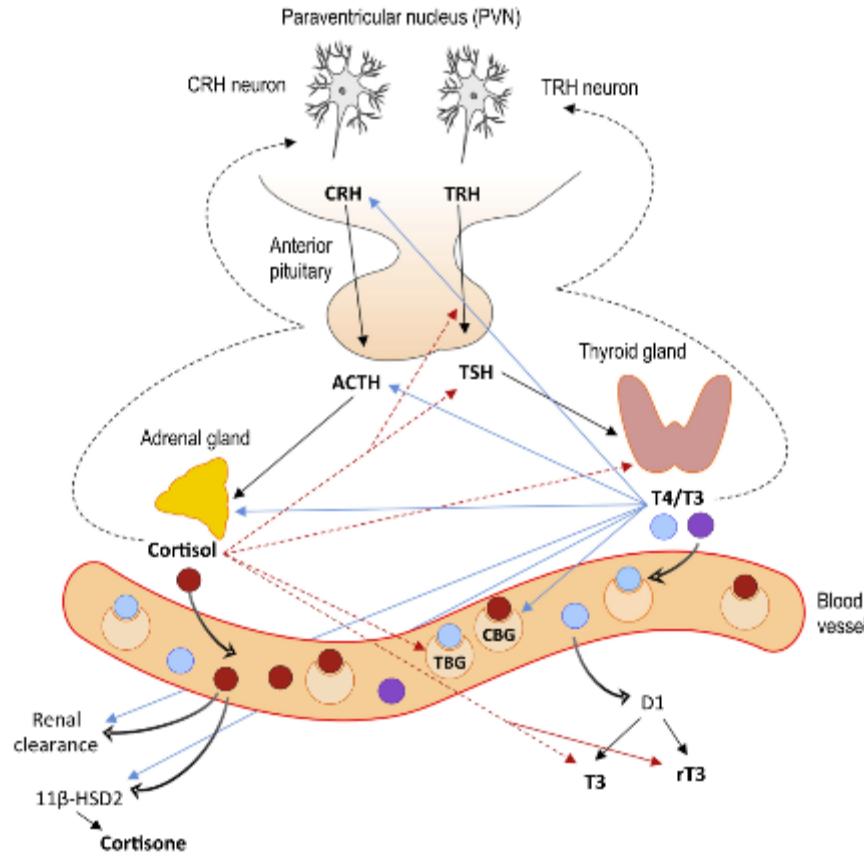

Solid lines represent positive associations, and dashed lines represent negative associations.

Cortisol:

- inhibitory effect on the release of TSH and THs (T<sub>4</sub> and T<sub>3</sub>)
- switch within D1 activity toward a preferential inactivation of T<sub>4</sub> into rT<sub>3</sub>

THs is associated with a general activation of the HPA axis:

Hypothesis: Depression is related to brain hypothyroidism together with systemic euthyroidism (Jackson, 1998), perhaps secondary to a cortisol-related decrease in D2 activity (Hidal and Kaplan, 1988).

N. K. Moog et al. / Neuroscience 342 (2017) 68–100

Interactive relationship between hormones of the hypothalamic–pituitary–thyroid axis (HPT) and the hypothalamic–pituitary–adrenal (HPA) axis. Depicted are the HPT and HPA axes and the regulatory circuits within the respective systems, as well as the effect of alterations on the level of the adrenal (red arrows) on HPT function and the thyroid (blue arrows) on HPA function. Solid lines represent positive associations, and dashed lines represent negative associations. Increased levels of cortisol have an inhibitory effect on the release of TSH from the pituitary and THs (T4 and T3) from the thyroid, as well as on the synthesis of the carrier protein TBG. Cortisol also promotes a switch within D1 activity toward a preferential inactivation of T4 into rT3, instead of an activation of T4 into T3. Increased availability of THs is associated with a general activation of the HPA axis on all levels and increased levels of the carrier protein CBG. However, THs also promote renal clearance and the metabolism of cortisol into its inactive form cortisone. Abbreviations: 11 $\beta$ -HSD2 = 11 $\beta$ -hydroxysteroid dehydrogenase 2; ACTH = adrenocorticotrophic hormone; CBG = cortisol-binding globulin; CRH = corticotropin-releasing hormone; D1 = deiodinase 1; rT3 = reverse T3; T3 = triiodothyronine; T4 = thyroxine; TBG = thyroxine-binding globulin; TRH = thyrotropin-releasing

In contrast to other forms of acute and chronic stress, stress associated with traumatic exposures (e.g. post-traumatic stress disorder (PTSD), childhood abuse) has generally been associated with an activation of thyroid function and thyrotoxicosis. As summarized by Wang (2006), elevated T3 concentrations have been reported in several samples of combat veterans with PTSD, including World War II, Vietnam, Israeli and Croatian samples. Increased T3 and/or decreased TSH levels were also found in civilian trauma patients (Olff et al., 2006)

GC administration decreases plasma TSH levels and attenuates the pituitary TSH response to TRH stimulation (Faglia et al., 1973; Banos et al., 1979; Ahlquist et al., 1989; Taylor et al., 1995).

A decrease in serum T3 is also observed in athyreotic patients on L-T4 substitution therapy (Duick et al., 1974; Chopra et al., 1975; Degroot and Hoye, 1976), which suggests that these changes are, at least in part, due to a GC-induced shift in the metabolism of T4, whereby

conversion of T4 to T3 is reduced in favor of a conversion of T4 to the inactive metabolite rT3. Effect of TH administration and thyroid dysfunction on HPA function. Conversely, administration of THs to rats produces hypertrophy of the adrenal gland and increases in corticotrophin-releasing hormone (CRH), ACTH and GC secretion and/or production (Boler and Moore, 1982; Shi et al., 1994; Johnson et al., 2005, 2013). The same phenomenon is seen in hyperthyroid patients (Felber et al., 1959; Hellman et al., 1961; Kenny et al., 1967), although there may be a decreased adreno-cortical reserve in the chronic state, which results in a lower GC response to ACTH stimulation (Tsatsoulis et al., 2000; Johnson et al., 2005). The effect of TH on HPA activity may be partly mediated by an increased metabolic clearance of cortisol from the blood in the hyper-thyroid state (Brown et al., 1958; Kenny et al., 1967), or the preferential metabolism of cortisol into its biologically inactive form, cortisone (indicated by increased urinary concentrations of the cortisone metabolite THE) (Hellman

The opposite phenomenon is seen in thyroidec-tomized or PTU-treated rats as well as in human patients with hypothyroidism. Absence of TH results in decreased adrenal weight (Kamilaris et al., 1991; Tohei, 2004), decreased production of CRH, ACTH and GCs (Hellman et al., 1961; Kenny et al., 1967; Fortier et al., 1970; Shi et al., 1994), a reduced adrenocortical response to ACTH (Kamilaris et al., 1991; Tohei, 2004), and a compensatory increase in the ACTH response to CRH (Kamilaris et al., 1991; Tohei, 2004). However, in the hypothyroid state there seems to be also a decreased clearance of cortisol (Br

The opposite phenomenon is seen in thyroidec-tomized or PTU-treated rats as well as in human patients with hypothyroidism. Absence of TH results in decreased adrenal weight (Kamilaris et al., 1991; Tohei, 2004)
